High performance PSR Power Switcher

1. Feature

Built-in TruePSR™ high-precision sampling technology
Built-in 650V high voltage NMOSFET switch
The peak output power up to 15W in universal
Precise primary side regulation accuracy is better than 2%
Precise primary side constant current accuracy is better than 3%
Output voltage drop compensation function with external resistance adjustment
Low switching loss full QR trough switch
Low standby consumption and high energy efficiency to meet the CoCV5 & DoE VI requirements
No-load standby power consumption as low as 50mW or less
Built-in CT-PSR™ active cycle tuning technology
Low-frequency start-up characteristic control optimizes the starting performance
Highly reliable low EMI gate drive with soft clamp
Built-in output over-voltage, short circuit and over-load protection
Optimized full-range audio-free operation
SOP7 package with reasonable layout

2. Applications

IT Equipment Charger
Power Adapter
Battery Charger
Open-frame Power

3. Description

The LN1F15 is a new generation of high-performance, highly integrated current-mode PSR power switch ICs that can easily build low-standby power consumption, high conversion efficiency, and low power dissipation to meet the energy efficiency standards of CoC V5 and DoE LEVEL VI in applications up to 12W with LiiSEMI's sync-rectifier ICs LN5S19, High-performance PSR primary side of the CC / CV switching power supply solutions. The chip has built-in high precision constant current and constant voltage control and has an optimized valley switch technology that provides output current error of better than ± 3% accuracy and ± 2% accuracy of output voltage error over the full range.

Switching frequencies of up to 70kHz allow the use of relatively small transformer size to complete the design, while a very small dead-time control allows the system to work in close to critical conduction mode to improve the utilization of the transformer, far superior to traditional PSR controller architecture.

With PWM / PFM / PBM mode multi-segment curve control mode of operation can further optimize the system under

different load conversion efficiency, especially at light load conversion efficiency, very light load conditions will automatically lock the peak current threshold to maintain efficient conversion, segmented modulation design makes the system with high conversion efficiency while effectively avoiding audible noise, the standby power consumption can be as low as 50mW the following.

The low-frequency start-up feature automatically operates once during each power-up and system reset to optimize startup characteristics and to reduce the impact of the switch on the high-voltage power switch. Soft-clamp gate drive control further removes high , While the active gate slope control significantly improves the level of switching interference. The new generation of cycle-rotation technology for PSR architecture makes the system extremely EMI-friendly.

The chip can also compensate for the output voltage drop through a specially designed linear output cable voltage drop compensation adjustment pin to improve the accuracy of the output voltage under load and maintain accurate load voltage from the load.

LN1F15 also provides a very complete protection circuit with automatic recovery, including cycle-by-cycle current limit (OCP), with high and low voltage compensation output overcurrent protection (OCP), VDD over-voltage protection and under voltage lockout (UVLO) .

Now available in halogen-free SOP7 standard green package.

12. Application and Implementation

The LN1F15 is a highly integrated, constant-current, constant-voltage PSR controller IC optimized for off-line applications below. Its highly efficient BM and QR hybrid mode control significantly reduces standby losses, improves conversion efficiency at light loads, and easily meets international energy efficiency standards such as CoC V5 and DoE LEVEL VI energy efficiency

12.1 Start-up current and start-up control

The LN1F15 can operate at very low start-up current conditions, with accurate UVLO control enabling fast and reliable power-up in a short period of time. Allowing a large start-up resistor value can significantly reduce the start-up power consumption, such as 4MΩ, although a 1/8W power-class resistor can meet the required power requirements, but must still carefully consider its ability to withstand voltage, The use of resistors in series is recommended, for example, using two 1206-type chip resistors in series.

The start-up resistor can be connected between the positive or AC input terminal of the input DC high voltage and the VDD storage capacitor. When the VDD voltage is charged to 21V after power-on, the internal circuit is started and the output drive pulse is finally set to GATE terminal, the system work begins.

12.2 Operating Current and VDD Capacitance

LN1F15 the normal operating current as low as 0.8mA, the IC itself when the loss is small, a capacity of not less than 3.3uF capacitor to meet the IC power supply and drive enough energy to consider the larger MOSFET input capacitance and wide Of the operating temperature range, should choose a lower internal resistance (ESR) of the capacitor type to open the MOSFET to provide fast and large current to speed up the MOSFET turn-on, in a typical system design recommended 4.7uF capacitor as VDD capacitance. In order to meet the maximum operating conditions of the VDD range, the capacitor voltage should be not less than 35V better. The effect of noise can be further reduced by connecting a non-polar capacitor in parallel to the VDD pin.

12.3 Cycleturning™ PSR (C.T. PSR)

The LN1F15 incorporates a proprietary, second-generation CycleTurning™ technology optimized for PSR that is clocked at the set time (CT-PSR) for the duration of the work cycle, resulting in a larger switching pulse spectrum To reduce the narrowband energy density, so that any single bandwidth within the average interference intensity greatly reduced. Therefore, the system in the EMI on the cost of the cost is greatly reduced.

12.4 Extended BM operating characteristics

The MOSFET switching loss ratio will increase significantly; while the switching loss and switching frequency is proportional to the lower switching frequency can significantly reduce the MOSFET switching losses. LN1F15 by detecting the VS voltage and time size, the system no-load or light load will automatically adjust the switching frequency to a lower value, the internal modulation voltage is lower than the set control voltage, the more the frequency decreases, but the more

The circuit automatically limits the frequency drop to a minimum of 22kHz to avoid audible noise.

When the system frequency drops to near 22KHz, if the modulation voltage is still lower than the set control voltage, the output will be disabled to ensure that the output voltage will not be too high, then the system will enter the BM mode to avoid audio noise, And as the load continues to reduce the number of pulses until the pulse into a single state, in order to optimize the system dynamic load response performance, the system will automatically lock the lowest equivalent switching frequency of 500Hz.

12.5 Current detection and leading edge blanking

The LN1F15 provides cycle-by-cycle current limiting, and the switching current is sampled into the IC through the current limiting resistor. The built-in leading-edge blanking eliminates current spikes into the IC, preventing current limiter malfunctions and preventing MOSFETs from being faulted, thus eliminating the need for a conventional external blanking circuit.

The maximum current limit threshold, the current comparator's maximum threshold voltage, is 0.75V.

12.6 Constant pressure control

LN1F15 by sampling the voltage waveform on the auxiliary winding, through a series of internal sampling chip, keep, analyze, deal with, produce the required various signals. Which compares the voltage signal with the internal reference voltage to generate a voltage error signal and adjusts the switch state according to the voltage error signal so as to compensate for the increase or decrease of the output load and the change of the output voltage caused by the increase or decrease of the input voltage, The typical output voltage (Vout) is:

$$V_{OUT} = (\frac{R_U}{R_D} + 1) * V_{CV} * \frac{N_S}{N_A} - VD$$

Here, Ru for the voltage sampling pull-up resistor, Rd for the voltage sampling pull-down resistor; Vcv for the internal voltage reference, typically 4.05V; Ns and Na are the transformer secondary winding turns and auxiliary winding turns; VD is output diode VF.

Through the unique TruePSR™ waveform analysis technology, the output voltage cannot be affected by the load current size to maintain high accuracy.

When the load continues to increase to the maximum operating state of the system but the sampled voltage is still lower than the internal reference voltage, the system will enter the constant current working state.

12.7 Constant current control

When the system enters the constant current output state, the LN1F15 will determine the proportional relation of the switching waveform by detecting the time parameter of the VS terminal waveform and keep the demagnetizing time T_{DIS} constant with the switching period by changing the dead time so that the output The current remains at a constant magnitude and the system's maximum demagnetization duty cycle (demagnetization time to switching period ratio) is 50%,

$$\frac{T_{DIS}}{T_{ON} + T_D + T_{DIS}} = \frac{T_{DIS}}{T} = 0.50$$

T_{ON} is the turn-on time; T_D is the dead time, the minimum is the main inductor resonant cycle of 1/4, for example 500kHz resonant period, T_D is about 0.5us; T_{DIS} for the transformer demagnetization time;

So the output constant current point Iout and the transformer turns ratio Np / Ns and the relationship between the primary peak switch current Ipeak:

$$I_{OUTCC} = 0.5 * I_{PEAK} * \frac{N_P}{N_S} * 0.50$$

For a given system, if the specified flyback voltage or turn ratio, according to the size of the output current constant according to the above formula to obtain the required primary peak switch current Ipeak size:

$$I_{PEAK} = \frac{N_S * I_{OUTCC}}{N_P * 0.25}$$

According to the obtained primary peak switch current value, the required current limiting resistance can be calculated according to the following formula:

$$R_{CS} = \frac{V_{CSMAX}}{I_{PEAK}}$$

Here, Vcsmax is the chip maximum current limit threshold, typically 0.75V.

12.8 Frequency control

LN1F15 by adjusting the switching pulse time parameters to automatically adjust the switching current size, and the corresponding control of the output state for a specified system, each time the switching frequency of the system are automatically balanced results, the system switching frequency is the transformer And the system together, when the output current constant according to the requirements of a reasonable set of transformer turns ratio and the system's maximum peak switching current, the maximum switching frequency will be determined by the transformer inductance, the typical maximum switching frequency:

$$F_{MAX} = \frac{2 * P_{OUT}}{I_{PEAK}^{\ 2} * L_P * h}$$

Here, Pout is the output constant current point corresponding to the maximum output power; Lp is the transformer primary inductance; η is the conversion efficiency.

The maximum operating frequency of the system should be set reasonably so that it does not exceed the maximum frequency limit (typical value is 70kHz) inside the chip, taking into account the effect of system switching loss and EMI. For general applications, the maximum switching frequency can be set between 35 ~ 60kHz. The recommended value is 55kHz for most applications.

In normal operation, the chip will automatically adjust the switching frequency or switching current according to the load size and input voltage to maintain a good conversion efficiency under various conditions, while avoiding audio noise, the typical switching frequency curve is as follows The figure shows:

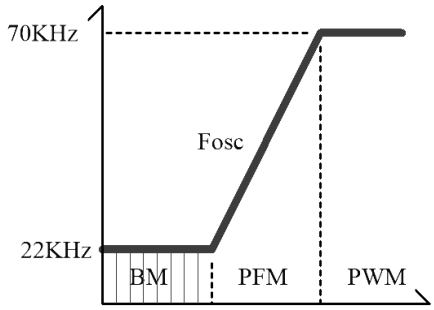

Fig4. Vea VS Fosc curve

12.9 QR control

The LN1F15 will set each turn-on action to a fixed position in the resonant period so that the current period can be automatically turned on in a reasonably designed system at the lower voltage position of each resonant waveform (best, the bottom of the resonant trough) Additional low turn-on loss characteristics can be achieved at light load conditions, further improving light-load efficiency.

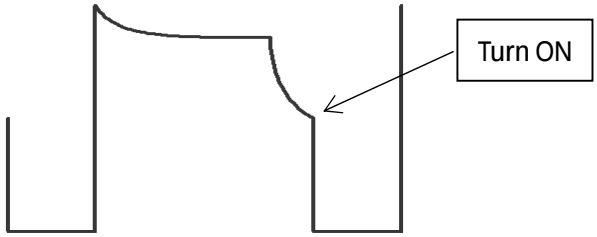

Fig5. QR mode

12.10 Startup characteristics

The LN1F15 will also ensure that the critical mode is active at every startup, allowing the system to start the process at a lower frequency and automatically increasing the operating frequency as the output voltage increases, so that the start-up does not occur as continuous Current-mode power supply current overshoot problem, which can effectively reduce the impact of starting current to reduce the power switch current stress.

12.11 Output wire voltage drop compensation

The LN1F15 features an excellent and easy-to-use output-wire voltage drop compensation technique. The compensation amplitude can be set by a simple external resistor. The output current can be linearly compensated when the output current is increased, thus completely canceling the output The voltage drop generated on the wire to achieve a very precise load voltage regulator output, while the maximum compensation from the internal fixed amplitude of 0.45V.

The ratio of the typical compensation voltage, V_{OCC}, to the output voltage, V_{OUT}, is K_{OCC}:

$$k_{OCC} = \frac{V_{OCC}}{V_{OUT}} = \frac{2315}{R_{OCC} + 28000}$$

R_{OCC} is the external compensation resistance in Ω.

12.12 Protective function

Excellent power systems require sophisticated fault protection to achieve high reliability. The LN1F15 is designed to meet a wide range of user requirements including cycle-by-cycle current limiting (OCP), output overload protection (OLP), VDD overvoltage lockout, and under-voltage lockout (UVLO).

When the VS terminal voltage more than 5V per unit of time more than twice or more than 1.45V more than twice the CS voltage will directly trigger the system into over-voltage protection and overcurrent protection state until the restart.

12.13 Built-in switch and heat treatment

The LN1F15 incorporates a high-switching-speed MOSFET power switch with a low RdsON voltage rating of 3A 650V to maintain low switching losses at switching frequencies as high as 65kHz, yet the chip operation will still produce a certain amount of power Heat, so the application should be carried out in the appropriate heat treatment, a simple approach is to chip in the PIN5 / 6 laying enough area of copper foil and tin treatment, as a cooling measures, a typical 10W application of copper foil area should not preferably less than 100 mm^2.

PCB layout should also ensure that high-voltage connection pin and other low-voltage pins or devices to maintain a sufficient safe distance, the minimum safe distance should be at least not less than 1mm is appropriate, so as to avoid damage caused by discharge.

13. Layout Guidelines

13.1 Principles of high-frequency layout

When switching power supply layout should follow the principle of high-frequency layout, Where possible, the current loop should be kept to a minimum. should be advanced and then out of the dual-capacitor and appropriate to maintain a single point of connection capacitance. Three typical current loops is shown in the following figure:

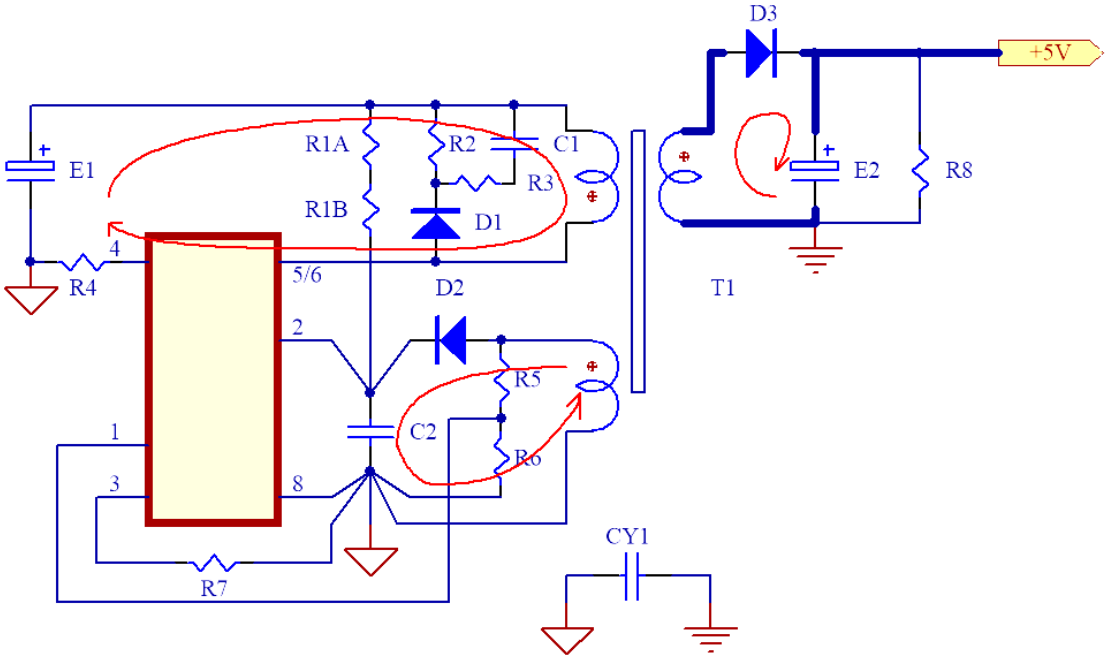

Fig6. Typical current loop diagram
